Abstract of FR 2741810 (A1)

The syringe consists of an elongated tube (212) containing the two substances (224,228) to be injected, separated by a piston (220) and situated between a front wall (232) equipped with a needle (240) and a rear wall (218) forming a piston, with an actuator. It also has a system (216) for mixing the two substances prior to injection. The rear wall is moved by a spring (308) with a retaining element and a stop, and its actuator comprises a spiral spring (286) round a tubular pusher (288) which has an open end surrounded by a collar (294).
